

The directory Data contains three files: census.dta, ecftse99.dta, and treatment.dta. The first contains variables for the entire Honduran census population (for variable definitions and their relation to the original census form, see the online appendix). The second contains the 1999 household survey used to calculate the probability of being poor. The third contains municipal-level data on the treatment status and height-for-age data.

To replicate the analyses, run Galiani&McEwan2013.do (the other .do file, povertypredict.do, is run from within this file).
